Business Process Explanation

Water Supply Fault Reporting and Repair Tracking

1. The Trigger and the Initial Report

The process begins when a resident notices a water supply problem, such as a leaking or burst pipe, an interruption, or low water pressure. The resident contacts the Call Center to report the fault. The Call Center Agent receives the report, records important details such as the location and description of the problem, and creates a new fault record in the database. The agent then checks whether the location and report details are complete. If information is missing, the agent requests the missing details from the resident. If the information is complete, the report proceeds to the Supervisor for review.

2. Supervisory Review and Assignment

The Supervisor reviews the reported fault and checks the water point's history to determine whether similar problems have occurred before. The Supervisor then assesses the severity of the fault. If it is a high-priority emergency, such as a major burst pipe, an emergency repair team is assigned. If it is a routine issue, the work is scheduled for standard maintenance. In either case, the database is updated to show that the fault status is Assigned.

3. The Technician's Work and Resolution

The Repair Technician visits the reported location, inspects the site, and performs the necessary repairs. After completing the work, the technician records the repair details in the system. This includes the work performed and the time taken. The database is updated to change the fault status to Repaired.

4. Verification and Closing the Loop

The Supervisor reviews the technician's work and verifies whether the problem has been fully resolved. If the issue remains, the fault ticket is reopened and returned to the technician for further inspection or repair. If the issue is resolved, the Supervisor closes the fault ticket and updates its database status to Closed. The resident is then notified that the repair is complete and the water supply has been restored.

5. How This Supports Management Decision-Making

Recording each stage of the process—from fault creation and assignment to repair completion and closure—gives management a clear history of reported faults and the time required to resolve them. Managers can use this information to identify areas or sectors with frequent leaks, recognize recurring problems, monitor repair-team performance, and plan maintenance resources. The records therefore support accountability, better planning, and more informed operational decisions.
